Safety instructions

These instructions are intended exclusively for authorised professionals. To avoid accidents and damage due to incorrect operation, carefully read through these operating instructions before you start working with the freshwater station. If you carry out any alterations to the construction of the freshwater station or the safety devices, you may invalidate your right to make guarantee claims. Always observe the local regulations.

Intended use

The freshwater station may only be installed in heating systems between the buffer tank and the drinking water circuit. The technical limit values specified in this manual must be considered. Incorrect use will result in the negation of any liability claims.

Electrical connection

Any electrical connections must be made by qualified electricians. Connection cables must be routed in the recesses provided in the insulated base in such a way that direct contact with the pump casing and the pipes is prevented.

Before switching on, check whether the supply voltage matches that stated on the power rating plates of the pump and the controller. All connections must correspond to the local regulations. Before opening the controller, all poles of the power supply must be isolated.

If you are connecting the FRISTAR 2 to an electrical system via a residual current device (RCD), use an RCD of type A which will detect pulsating direct currents and bears the following marking:

Checking using a high voltage insulation tester may cause damage to the pump and the control electronics.

Safety standards during installation, commissioning and maintenance

Installation, commissioning and maintenance may only be carried out by qualified persons who are familiar with these operating instructions.

Before you start work on the system, ensure that the system is switched off and all components are cooled down. When replacing the pump, turn the 4 ball valves into the closed position.

In multi-occupancy dwellings, legionella protection must be observed in accordance with the local regulations.

WARNING! Dependent on the pump and system operating conditions, the surface temperatures can be very high. Direct contact with the pump or pipes can result in burns!
Mode of operation

Through use of the instantaneous heating concept, drinking water is heated both hygienically and with low energy consumption in the FRISTAR freshwater station.

If water is drawn from the mains, the primary circuit pump transports tank water from a buffer tank through the plate heat exchanger. On the secondary side of the heat exchanger the drinking water flowing through is heated to the set temperature. The cooled tank water is returned to bottom layer of the buffer tank.

The speed control of the primary circuit pump is performed in the FRISTAR 2 controller based on the measurements made by the volume flow sensor in the cold water line (flow rate $V_{KW}$ and temperature $T_{KW}$) and the temperature sensors in the hot water line ($T_{WW}$) and in the primary flow ($T_{Pri}$). The pumps are controlled by means of PWM signals. The optimum matching of the control behaviour to the pump and the heat exchanger guarantees perfect constant maintenance of the outlet temperature.

Hydraulic circuit diagram
Components

- Primary sensor
- Controller
- Volume flow sensor
- Hot water sensor
- Plate heat exchanger
- Ventilation primary circuit
- Ball valve
- Cold water secondary circuit
- Ball valve
- Circulation pipe connection
- Ball valve with gravity brake
- Hot water secondary circuit
- Cold water secondary circuit
- Return primary circuit
- Pump
Installation

Preparation

- A safety valve (max. 6 bar) must be installed in the cold water supply corresponding to standards DIN 1988 and 4753, part 1 and TRD 721.
- If the cold water pressure > 6 bar, fit a diaphragm pressure reducer max. 6 bar.
- The installation of flushing equipment before and after the plate heat exchanger in the primary and secondary circuits is recommended for descaling or cleaning as necessary.

Special accessories: VMS pre-mixing set

If the tank is operated at a temperature higher than 70 °C a pre-mixer that restricts the temperature to less than 70 °C must be used in the primary circuit.

In order to prevent damage from calcification, the maximum pre-mixing temperature must be 70 °C with a water hardness of up to 10 °dH, 65 °C with up to 15 °dH and 60 °C at most with a hardness above 15 °dH.

The VMS pre-mixing set is suitable for both FRISTAR models (left pump, right pump).

Dimensions

Housing dimensions (thermal insulation cover)
W x H x D = 366 x 811 x 158 mm

Weight (freshwater module incl. controller and thermal insulation cover)
19.64 kg
Interchanging connections
For optimum matching of the pipelines to the freshwater station it is possible to interchange the connections (right/left). Doing this does not change the circulation line heat exchanger openings or the venting of the primary circuit.

**Procedure:**
1. Demounting of pipe elements 1 - 4 including pump from the heat exchanger
2. Removal of the pump and installation in the correct position.
3. Remount pump connection plug 5 on the other side.
4. Mounting of pipe elements 1 - 4 and the pump on the heat exchanger (see figures above) on the other side, correct positional setup of the volume flow sensor
5. Commissioning according to the "Commissioning" chapter

**Important:** The primary and secondary connections must be exchanged together!
Installation

- Mounting position: Only **vertical**
- Installation with the heat exchanger at the top/above the controller (acc. to diagrams) is recommended.
- Pull off the cowling in a forwards direction.
- If necessary: Interchange the right/left connections (see chapter "Interchanging connections").
- Mark the fastening points, insert rawl plugs, fasten the station to the wall.
- Fitting and connection of the pipe connections (3/4” outside thread connector). Plan for as short as possible pipes in the primary circuit (tank -> freshwater station).
- Electrical connection
  The freshwater station is pre-wired ready for installation, connection to the electricity mains takes place on site:
  - using a plug in a wall socket or
  - using a double pole isolator with a permanent connection.

Commissioning

- Before filling the system, thoroughly flush both the primary and secondary side systems. To do this the locking bolt of the return valve with the gravity brake is placed in a 45° position so that it is non-operational.
- **Slowly** fill the house system with drinking water via the secondary side ball valves.
- Vent the house system at the draw-off valves.
- **Slowly** fill the system with hot water via the ball valves in the primary flow.
- Vent the primary circuit using the venting opening of the plate heat exchanger.
- Set the pump to continuous operation and check pump running. Audible background noise during operation of the circulating pump indicates air in the system.
  **Warning!** Only start the pump when it is filled.
- Check all connections, including in the freshwater station, for correct seating and leak-tightness. If necessary, retighten to the necessary torque.
- Activate the gravity brake at the primary system return valve (place locking bolt vertically)
- If a DHW circulation pump is used: Set the runtime on the potentiometer inside the controller. (Caution: switch off the 230 V power supply before opening the controller!)
- Place the cowling on the bottom part
- Set the pump in automatic mode and select the setpoint temperature.
Connection of a circulation line

Activating the DHW circulation pump using the FRISTAR 2 controller

Hydraulic circuit diagram with circulation line

Circulation pump (optional)

If an external DHW circulation pump is connected directly to the FRISTAR 2 controller, it will operate in pulse mode. When water is drawn off, the DHW circulation pump runs for the time set on the potentiometer (0 to approx. 10 minutes max.). After the end of the run time, pump start-up is permitted only after a 10 minutes break.

If a DHW circulation pump is not used, the potentiometer must be set to 0 (= factory setting), as otherwise the primary pump would run on for the set time after every draw-off.

The plate heat exchanger is provided with a connection for a circulation line. To lead the circulation line through to the heat exchanger, the isolation cap must be cut out to suitable dimensions.
Activating the DHW circulation pump using a different switching device

For the primary pump to be enabled when the DHW circulation pump is running, the DHW circulation return must be connected in the cold water inlet.

However, it must be ensured that the flow rate in the DHW circulation line is greater than the flow sensor minimum flow rate (2 l/min or 120 l/h).

Hydraulic circuit diagram with circulation line

When the DHW circulation pump is switched on, the sensor (Vkw) measures the flow rate and the primary pump is enabled.
Cascade switching

The FRISTAR 2 is designed for a maximum water draw-off of 30 l/min. For a greater draw-off of domestic hot water, multiple freshwater stations can be used in a cascade.

The first module is fed directly, all others stations are added with stop valves, if necessary. These valves must open or close in at least 30 seconds. The UDV universal 3-way valve from Technische Alternative is excellent for this purpose.

Valves are added via overriding controller with a volume flow sensor that measures the total volume flow. With up to 3 modules, the FTS5-85DL sensor is adequate; with 4-5 modules, the FTS9-150DL sensor must be used.

The sensors in the FRISTAR stations should not be subjected to more than 30 litres per minute. The final station, however, should be flushed several times a day to prevent stagnant water from forming. This is ensured if the overriding controller increases the station number in stages of about 8-10 l/min.

In the following "step-by-step" instructions, the first stage with 9 l/min was selected because sensor FTS9-150DL is activated properly starting at 9 l/min only.

A three circuit controller UVR61-3R (or UVR63) can switch the modules. Cascade control can of course also be integrated into the programs of the UVR1611, UVR16x2 or RSM610 controllers.

Hydraulic circuit diagram of a cascade with four FRISTAR fresh water stations

Figure with fresh water stations version, version "Pump on the right"

The initial designations for stop valves A1 – A3 refer to controllers UVR61-3R or UVR63.
Cascade switching control with UVR61-3R or UVR63
Controllers UVR61-3R and UVR63 have exactly the same settings.

</tbody>
</table>

The 3 outputs A1, A2 and A3 for the shut-off valves are switched on if the corresponding flow rate thresholds min1 (540 l/h), min2 (960 l/h) and min3 (1440 l/h) are exceeded.
The three outputs A1, A2 and A3 for the stop valves are switched on if the associated flow thresholds \( \text{min}_1 \) (540 l/h), \( \text{min}_2 \) (960 l/h) and \( \text{min}_3 \) (1440 l/h) are exceeded. The \( \text{min}_3 \) threshold can be set to a maximum of 150.0 °C (= 1500 l/h) in these controllers.

**Control of cascade switching with UVR1611, UVR16x2 or RSM610**

The outputs for the stop valves are switched on by comparison functions, with one comparison function for each valve. The relevant switch-on and switch-off thresholds should be chosen in the same way as for the UVR61-3R.

**Cascade switching with circulation line**

**Schematic diagram for activating the DHW circulation pump with the FRISTAR 2 controller**

Figure with fresh water stations version, version "Pump on the right"

The circulation pump is connected only to the always ready FRISTAR 2.
**Schematic diagram for activating the DHW circulation pump with a different switching device**

If the DHW circulation pump is switched via a different controller, the DHW circulation return must be connected to the cold water supply line.

However, it must be ensured that the flow rate in the DHW circulation line is greater than the minimum flow rate of the flow sensor in the FRISTAR 2 (2 l/min or 120 l/h).

**UVR61-3R or UVR63**

If the DHW circulation pump is also to be switched on and off according to temperature, the maximum possible number of FRISTAR 2 modules is three. This is done using the program 480 for switching modules 2 and 3 on and off via outputs A1 and A2. The DHW circulation pump can be switched at output A3 via the differential S5 – S4 (S5 is unused, S4 measures the DHW circulation temperature and switches off when the max3 value is reached).

**UVR1611, UVR16x2 or RSM610**

The circulation pump can be controlled with the "circulation" function.
Data transfer with DL bus

The FRISTAR 2 controller can be connected to the DL bus. The DL bus allows the sensor values, the set value and the heat meter values to be adopted via DL inputs on the TA controllers. This also makes logging of the values possible.

With the UVR16x2 and RSM610 controllers, a set value can be issued via a DL output which will overwrite the setting on the FRISTAR controller.

Upon querying by the FRISTAR 2 controller (ESR21, UVR61-3 and UVR63H from version 5.0, ESR31, UVR63, UVR1611 from version A3.00 and serial number 13286 as well as UVR16x2 or RSM610), the FRISTAR controller returns the corresponding measured value.

The request is made up of the DL address of the FRISTAR 2 controller and index of the value.

The address is specified on the PCB of the FRISTAR 2 controller by breaking the conductors which are labelled 1, 2 and 4. These are located on the outer PCB edge. If none of the conductors are cut, the FRISTAR 2 controller is assigned address 1 (factory setting). Provided no other sensors are connected to the DL bus, no change of address is required.

The new address is derived from address 1 (= factory setting) plus the sum of all the cut through values.

Example: required address 6 = 1 (from factory setting) + 1 + 4

= conductors 1 and 4 must be cut.

The index of the respective values is fixed:

<table>

</tbody>
</table>

**TAPPS 2 – Programming UVR1611:**

1. **O14** Data link

2. Analogue network input

3. Source: DL

4. Sensor address

5. Index of the measured value

A still unused network input variable must be selected for each new value.

**ESR21, ESR31, UVR61-3, UVR63, UVR63H:**

Adjustment of the measurements takes place in the menu **EXT DL** (external sensors)

**Example:** The external sensor 1 has address 1; the value of the volume flow should be adopted (index 2).

**UVR65**

In the expert level under "Ext. sensors", DL bus is specified as the source for one of the inputs and the DL address of the FRISTAR2-WP controller is specified. The required index according to the table on the previous page should be entered underneath.
**Electrical connection**

Connection S1: Primary flow sensor TPri
Connection S2: Hot water sensor TW

The polarity of the DL bus connections (DL and "Earth") is **not** interchangeable and must be observed.

**Safety instructions**

If you are connecting the FRISTAR 2 to an electrical system via a **residual current device** (RCD), use an RCD of **type A** which will detect **pulsating direct currents** and bears the following marking:

![Residual current device symbol]

Checking using a high voltage insulation tester may cause damage to the pump and the control electronics.
**Operation of the controller and LED indicators**

Operation of the controller has been kept as simple as possible, so that it can also be operated by inexperienced users.

The temperature can only be selected on the FRISTAR controller if no set value has been issued by a UVR16x2 or RSM 610 controller via the DL bus.

**Manual-automatic changeover switch**

Pressure loss characteristic curve of plate heat exchanger

The pump operates in heating mode, meaning that at a 5 % PWM value, the pump will run at full speed. A break in the PWM lead therefore results in full pump speed.

The eight curves shown correspond to the following PWM values: 5 % (max.), 20 %, 31 %, 41 %, 52 %, 62 %, 73 %, 88 % (min.).

The corrosion behaviour of stainless steel and copper solder must be considered.
Tips on troubleshooting

The following troubleshooting approaches may help in the event of faulty operation, but before working on the freshwater module, it is always important to ensure that it is at zero volt and that no hot pipe temperatures can occur.

Other possible solutions:
- Check temperature sensors (sensors and wiring)
- Check cable connection between controller and flow sensor
- Check water pressure on secondary side
- Check flow sensor for contamination
- Check position of set value adjuster (may be twisted by 180°)

---

**Flowchart Diagram**

1. **Status LED illuminated?**
   - **Illuminated green**
     - **Illuminated/flashing differently**
       - See table "LED status indication" on page 21
     - **Not illuminated**
       - Check power supply, check circuit breaker, check connecting cable and clamping

2. **Is the pump running in manual mode?**
   - **Running**
     - **Not running**
       - Check pump cable (power supply and PWM) to pump and terminal, check pump for seizing (corrosion)

3. **Is DHW available after manual mode?**
   - **DHW avail.**
     - Check flow switch cable
   - **DHW not avail.**
     - Vent primary side, check valves
EU Declaration of conformity

Document- Nr. / Date: TA18002 / 25.06.2018
Company / Manufacturer: Technische Alternative RT GmbH
Address: A- 3872 Amaliendorf, Langestraße 124

This declaration of conformity is issued under the sole responsibility of the manufacturer.

Product name: FRISTAR 2-WP
Product brand: Technische Alternative RT GmbH
Product description: Fresh water station

The object of the declaration described above is in conformity with Directives:

2014/35/EU Low voltage standard
2014/30/EU Electromagnetic compatibility
2011/65/EU RoHS Restriction of the use of certain hazardous substances
2009/125/EC Eco-design directive

Employed standards:
EN 60730-1: 2011 Automatic electrical controls for household and similar use – Part 1: General requirements
EN 61000-6-3: 2007 Electromagnetic compatibility (EMC) - Part 6-3: Generic standards - Emission standard for residential, commercial and light-industrial environments
+ A1: 2011
+ AC2012
EN 61000-6-2: 2005 Electromagnetic compatibility (EMC) - Part 6-2: Generic standards - Immunity for industrial environments
+ AC2005
EN 50581: 2012 Technical documentation for the assessment of electrical and electronic products with respect to the restriction of hazardous substances

Position of CE - label: On packaging, manual and type label

Issuer: Technische Alternative RT GmbH
A- 3872 Amaliendorf, Langestraße 124

This declaration is submitted by

Dipl.-Ing. Andreas Schneider, General manager,
02/02/2017

This declaration certifies the agreement with the named standards, contains however no warranty of characteristics.
The security advices of included product documents are to be considered.
 Guarantee conditions

Note: The following guarantee conditions do not in any way limit the legal right to a guarantee, rather expand your rights as a consumer.

1. The company Technische Alternative RT GmbH provides a two-year guarantee from the date of purchase for all the devices and parts which it sells. Defects must be reported immediately upon detection and within the guarantee period. Technical support knows the correct solution for nearly all problems. In this respect, contacting us immediately will help to avoid unnecessary expense or effort in troubleshooting.

2. The guarantee includes the free of charge repair (but not the cost of on-site fault-finding, removal, refitting and shipping) of operational and material defects which impair operation. In the event that a repair is not economically worthwhile according to the assessment of Technische Alternative, the goods will be replaced.

3. Not included is damage resulting from the effects of overvoltages or abnormal ambient conditions. Likewise, no guarantee liability can be accepted if the device defect is due to: transport damage for which we are not responsible, incorrect installation and assembly, incorrect use, non-observance of operating and installation instructions or incorrect maintenance.

4. The guarantee claim will expire if repairs or actions are carried out by persons who are not authorised to do so or have not been so authorised by us or if our devices are operated with spare, supplementary or accessory parts which are not considered to be original parts.

5. The defective parts must be sent to our factory with an enclosed copy of the proof of purchase and a precise description of the defect. Processing is accelerated if an RMA number is applied for via our home page www.ta.co.at. A prior clarification of the defect with our technical support is necessary.

6. Services provided under guarantee result neither in an extension of the guarantee period nor in a resetting of the guarantee period. The guarantee period for fitted parts ends with the guarantee period of the whole device.

7. Extended or other claims, especially those for compensation for damage other than to the device itself are, insofar as a liability is not legally required, excluded.
